Background

A 2025 Children's Oncology Group (COG) study¹ found that Black and Hispanic children with high-risk neuroblastoma had worse overall survival (OS), even when treated with the same standardized protocols on frontline COG clinical trials. The mechanisms explored in the study did not fully account for the observed disparities in survival. With the NCCR Data Platform, we now have the opportunity to examine whether similar patterns exist among children who did not participate in a COG clinical trial.

Methods

The NCCR Data Platform links Surveillance, Epidemiology, and End Results (SEER) population-based cancer registry data from 1995 to 2021, representing 57.6% of all US children, adolescents and young adults, and data from patients enrolled in COG studies from 2007 to 2018, including clinical trials and registry protocols. For this study, we will use SEER population-based cancer registry data from 2007 to 2018 to align with the available COG data. Survival rates will be estimated using Kaplan-Meier analysis. Univariate analysis will be performed with the log-rank test, and multivariate analysis will utilize Cox proportional hazards regression to identify factors associated with overall survival (OS). The analysis will be performed using SEER*Stat and R/RStudio.

Results/Conclusion

This analysis will help determine whether racial and ethnic disparities in survival among children with neuroblastoma extend beyond the clinical trial population. The study will also evaluate other factors associated with survival. By comparing outcomes in trial and non-trial settings, we aim to better understand the role of broader contextual and systemic factors. Results may inform future strategies to improve equity in pediatric oncology outcomes. This study will also highlight the depth and utility of the NCCR Data Platform as a resource for population-based cancer research
